GHSA-m425-mq94-257g	<p>gRPC-Go HTTP/2 Rapid Reset vulnerability</p> <p>### Impact</p> <p>In affected releases of gRPC-Go, it is possible for an attacker to send HTTP/2 requests, cancel them, and send subsequent requests, which is valid by the HTTP/2 protocol, but would cause the gRPC-Go server to launch more concurrent method handlers than the configured maximum stream limit.</p> <p>### Patches</p> <p>This vulnerability was addressed by #6703 and has been included in patch releases: 1.56.3, 1.57.1, 1.58.3. It is also included in the latest release, 1.59.0.</p> <p>Along with applying the patch, users should also ensure they are using the `grpc.MaxConcurrentStreams` server option to apply a limit to the server's resources used for any single connection.</p> <p>### Workarounds</p> <p>None.</p> <p>### References</p> <p>#6703</p>	<p>V2: 7</p> <p>V3: 7.5</p>	<p>go:google.golang.org/grpc</p> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>1.57.0</td><td>1.56.3;1.57.1;1.58.3</td></tr></table>	Impacted Version	Fixed Version	1.57.0	1.56.3;1.57.1;1.58.3	<p>Oct 25, 2023 05:17:37</p>	<p>Containers</p> <p>coredns-7db6d8ff4d-8tkdq</p>

CVE-2024-7264	<p>libcurl's ASN1 parser code has the `GTime2str()` function, used for parsing an ASN.1 Generalized Time field. If given a syntactically incorrect field, the parser might end up using -1 for the length of the *time fraction*, leading to a `strlen()` getting performed on a pointer to a heap buffer area that is not (purposely) null terminated. This flaw most likely leads to a crash, but can also lead to heap contents getting returned to the application when [CURLINFO_CERTINFO](https://curl.se/libcurl/c/CURLINFO_CERTINFO.html) is used.</p>	<p>V2: 4</p> <p>V3: 6.5</p>	<p>curl</p> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>7.81.0-1ubuntu1.16</td><td>7.81.0-1ubuntu1.17</td></tr></table> <p>curl/libcurl4</p> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>7.81.0-1ubuntu1.16</td><td>7.81.0-1ubuntu1.17</td></tr></table>	Impacted Version	Fixed Version	7.81.0-1ubuntu1.16	7.81.0-1ubuntu1.17	Impacted Version	Fixed Version	7.81.0-1ubuntu1.16	7.81.0-1ubuntu1.17	<p>Aug 12, 2024 01:30:51</p>	<p>Nodes</p> <p>minikube</p>

CVE-2024-6387	A security regression (CVE-2006-5051) was discovered in OpenSSH's server (sshd). There is a race condition which can lead sshd to handle some signals in an unsafe manner. An unauthenticated, remote attacker may be able to trigger it by failing to authenticate within a set time period.	V2: 7 V3: 8.1	openssh/openssh-client	Jul 29, 2024 10:15:08	Nodes minikube

CVE-2024-5535	<p>Issue summary: Calling the OpenSSL API function <code>SSL_select_next_proto</code> with an empty supported client protocols buffer may cause a crash or memory contents to be sent to the peer. Impact summary: A buffer overread can have a range of potential consequences such as unexpected application behaviour or a crash. In particular this issue could result in up to 255 bytes of arbitrary private data from memory being sent to the peer leading to a loss of confidentiality. However, only applications that directly call the <code>SSL_select_next_proto</code> function with a 0 length list of supported client protocols are affected by this issue. This would normally never be a valid scenario and is typically not under attacker control but may occur by accident in the case of a configuration or programming error in the calling application. The OpenSSL API function <code>SSL_select_next_proto</code> is typically used by TLS applications that support ALPN (Application Layer Protocol Negotiation) or NPN (Next Protocol Negotiation). NPN is older, was never standardised and is deprecated in favour of ALPN. We believe that ALPN is significantly more widely deployed than NPN. The <code>SSL_select_next_proto</code> function accepts a list of protocols from the server and a list of protocols from the client and returns the first protocol that appears in the server list that also appears in the client list. In the case of no overlap between the two lists it returns the first item in the client list. In either case it will signal whether an overlap between the two lists was found. In the case where <code>SSL_select_next_proto</code> is called with a zero length client list it fails to notice this condition and returns the memory immediately following the client list pointer (and reports that there</p>	<div>V2: 9</div> <div>V3: 9.1</div>	<div>openssl</div> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>3.0.2-0ubuntu1.15</td><td>3.0.2-0ubuntu1.17</td></tr></table> <div>openssl/libssl3</div> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>3.0.2-0ubuntu1.15</td><td>3.0.2-0ubuntu1.17</td></tr></table>	Impacted Version	Fixed Version	3.0.2-0ubuntu1.15	3.0.2-0ubuntu1.17	Impacted Version	Fixed Version	3.0.2-0ubuntu1.15	3.0.2-0ubuntu1.17	<div>Jul 12, 2024</div> <div>10:15:16</div>	<div>Nodes</div> <div>minikube</div>

	<p>was no overlap in the lists). This function is typically called from a server side application callback for ALPN or a client side application callback for NPN. In the case of ALPN the list of protocols supplied by the client is guaranteed by libssl to never be zero in length. The list of server protocols comes from the application and should never normally be expected to be of zero length. In this case if the SSL_select_next_proto function has been called as expected (with the list supplied by the client passed in the client/client_len parameters), then the application will not be vulnerable to this issue. If the application has accidentally been configured with a zero length server list, and has accidentally passed that zero length server list in the client/client_len parameters, and has additionally failed to correctly handle a "no overlap" response (which would normally result in a handshake failure in ALPN) then it will be vulnerable to this problem. In the case of NPN, the protocol permits the client to opportunistically select a protocol when there is no overlap. OpenSSL returns the first client protocol in the no overlap case in support of this. The list of client protocols comes from the application and should never normally be expected to be of zero length. However if the SSL_select_next_proto function is accidentally called with a client_len of 0 then an invalid memory pointer will be returned instead. If the application uses this output as the opportunistic protocol then the loss of confidentiality will occur. This issue has been assessed as Low severity because applications are most likely to be vulnerable if they are using NPN instead of ALPN - but NPN is not widely used. It also requires an application configuration or programming error.</p>

	Finally, this issue would not typically be under attacker control making active exploitation unlikely. The FIPS modules in 3.3, 3.2, 3.1 and 3.0 are not affected by this issue. Due to the low severity of this issue we are not issuing new releases of OpenSSL at this time. The fix will be included in the next releases when they become available.

CVE-2024-4603	<p>Issue summary: Checking excessively long DSA keys or parameters may be very slow. Impact summary: Applications that use the functions <code>EVP_PKEY_param_check()</code> or <code>EVP_PKEY_public_check()</code> to check a DSA public key or DSA parameters may experience long delays. Where the key or parameters that are being checked have been obtained from an untrusted source this may lead to a Denial of Service. The functions <code>EVP_PKEY_param_check()</code> or <code>EVP_PKEY_public_check()</code> perform various checks on DSA parameters. Some of those computations take a long time if the modulus (<code>`p`</code> parameter) is too large. Trying to use a very large modulus is slow and OpenSSL will not allow using public keys with a modulus which is over 10,000 bits in length for signature verification. However the key and parameter check functions do not limit the modulus size when performing the checks. An application that calls <code>EVP_PKEY_param_check()</code> or <code>EVP_PKEY_public_check()</code> and supplies a key or parameters obtained from an untrusted source could be vulnerable to a Denial of Service attack. These functions are not called by OpenSSL itself on untrusted DSA keys so only applications that directly call these functions may be vulnerable. Also vulnerable are the OpenSSL <code>pkey</code> and <code>pkeyparam</code> command line applications when using the <code>`-check`</code> option. The OpenSSL SSL/TLS implementation is not affected by this issue. The OpenSSL 3.0 and 3.1 FIPS providers are affected by this issue.</p>	<div>V2: 4</div> <div>V3: 5.3</div>	<div>openssl</div> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>3.0.2-0ubuntu1.15</td><td>3.0.2-0ubuntu1.17</td></tr></table> <div>openssl/libssl3</div> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>3.0.2-0ubuntu1.15</td><td>3.0.2-0ubuntu1.17</td></tr></table>	Impacted Version	Fixed Version	3.0.2-0ubuntu1.15	3.0.2-0ubuntu1.17	Impacted Version	Fixed Version	3.0.2-0ubuntu1.15	3.0.2-0ubuntu1.17	<div>Aug 13, 2024</div> <div>12:35:05</div>	<div>Nodes</div> <div>minikube</div>

CVE-2024-33599	nscd: Stack-based buffer overflow in netgroup cache If the Name Service Cache Daemon's (nscd) fixed size cache is exhausted by client requests then a subsequent client request for netgroup data may result in a stack-based buffer overflow. This flaw was introduced in glibc 2.15 when the cache was added to nscd. This vulnerability is only present in the nscd binary. CVE-2024-2511	Issue summary: Some non-default TLS server configurations can cause unbounded memory growth when processing TLSv1.3 sessions Impact summary: An attacker may exploit certain server configurations to trigger unbounded memory growth that would lead to a Denial of Service This problem can occur in TLSv1.3 if the non-default SSL_OP_NO_TICKET option is being used (but not if early_data support is also configured and the default anti-replay protection is in use). In this case, under certain conditions, the session cache can get into an incorrect state and it will fail to flush properly as it fills. The session cache will continue to grow in an unbounded manner. A malicious client could deliberately create the scenario for this failure to force a Denial of Service. It may also happen by accident in normal operation. This issue only affects TLS servers supporting TLSv1.3. It does not affect TLS clients. The FIPS modules in 3.2, 3.1 and 3.0 are not affected by this issue. OpenSSL 1.0.2 is also not affected by this issue. CVE-2024-22189	<p>QUIC's Connection ID Mechanism vulnerable to Memory Exhaustion Attack</p> <p>An attacker can cause its peer to run out of memory by sending a large number of NEW_CONNECTION_ID frames that retire old connection IDs. The receiver is supposed to respond to each retirement frame with a RETIRE_CONNECTION_ID frame. The attacker can prevent the receiver from sending out (the vast majority of) these RETIRE_CONNECTION_ID frames by collapsing the peers congestion window (by selectively acknowledging received packets) and by manipulating the peer's RTT estimate.</p> <p>I published a more detailed description of the attack and its mitigation in this blog post: https://seemann.io/posts/2024-03-19-exploiting-quics-connection-id-management/.</p> <p>I also presented this attack in the IETF QUIC working group session at IETF 119: https://youtu.be/JqXtYcZAtIA?si=nJ31QKLBSTRXY35U&t=3683</p> <p>There's no way to mitigate this attack, please update quic-go to a version that contains the fix.</p>	<div>V2: 7</div> <div>V3: 7.5</div>	<div>go:github.com/quic-go/quic-go</div> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>0.37.4</td><td>0.42.0</td></tr></table>	Impacted Version	Fixed Version	0.37.4	0.42.0	<div>Apr 2, 2024</div> <div>10:16:05</div>	<div>Containers</div> <div>coredns-7db6d8ff4d-8tkdq</div>

CVE-2024-0727	<p>Issue summary: Processing a maliciously formatted PKCS12 file may lead OpenSSL to crash leading to a potential Denial of Service attack Impact summary: Applications loading files in the PKCS12 format from untrusted sources might terminate abruptly. A file in PKCS12 format can contain certificates and keys and may come from an untrusted source. The PKCS12 specification allows certain fields to be NULL, but OpenSSL does not correctly check for this case. This can lead to a NULL pointer dereference that results in OpenSSL crashing. If an application processes PKCS12 files from an untrusted source using the OpenSSL APIs then that application will be vulnerable to this issue. OpenSSL APIs that are vulnerable to this are: PKCS12_parse(), PKCS12_unpack_p7data(), PKCS12_unpack_p7encdata(), PKCS12_unpack_authsafes() and PKCS12_newpass(). We have also fixed a similar issue in SMIME_write_PKCS7(). However since this function is related to writing data we do not consider it security significant. The FIPS modules in 3.2, 3.1 and 3.0 are not affected by this issue.</p>	<div>V2: 4</div> <div>V3: 5.5</div>	<div>openssl/libssl3</div> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>3.0.11-1~deb12u2</td><td>3.0.13-1~deb12u1</td></tr></table>	Impacted Version	Fixed Version	3.0.11-1~deb12u2	3.0.13-1~deb12u1	<div>May 1, 2024</div> <div>02:15:13</div>	<div>Containers</div> <div>kube-proxy-kvh2j</div>

CVE-2024-0397	A defect was discovered in the Python “ssl” module where there is a memory race condition with the ssl.SSLContext methods “cert_store_stats()” and “get_ca_certs()”. The race condition can be triggered if the methods are called at the same time as certificates are loaded into the SSLContext, such as during the TLS handshake with a certificate directory configured. This issue is fixed in CPython 3.10.14, 3.11.9, 3.12.3, and 3.13.0a5. CVE-2023-6597	An issue was found in the CPython `tempfile.TemporaryDirectory` class affecting versions 3.12.1, 3.11.7, 3.10.13, 3.9.18, and 3.8.18 and prior. The tempfile.TemporaryDirectory class would dereference symlinks during cleanup of permissions-related errors. This means users which can run privileged programs are potentially able to modify permissions of files referenced by symlinks in some circumstances. CVE-2023-6237	<p>Issue summary: Checking excessively long invalid RSA public keys may take a long time. Impact summary: Applications that use the function EVP_PKEY_public_check() to check RSA public keys may experience long delays. Where the key that is being checked has been obtained from an untrusted source this may lead to a Denial of Service. When function EVP_PKEY_public_check() is called on RSA public keys, a computation is done to confirm that the RSA modulus, n, is composite. For valid RSA keys, n is a product of two or more large primes and this computation completes quickly. However, if n is an overly large prime, then this computation would take a long time. An application that calls EVP_PKEY_public_check() and supplies an RSA key obtained from an untrusted source could be vulnerable to a Denial of Service attack. The function EVP_PKEY_public_check() is not called from other OpenSSL functions however it is called from the OpenSSL pkey command line application. For that reason that application is also vulnerable if used with the '-pubin' and '-check' options on untrusted data. The OpenSSL SSL/TLS implementation is not affected by this issue. The OpenSSL 3.0 and 3.1 FIPS providers are affected by this issue.</p>	<div>V2: 4</div> <div>V3: 5.9</div>	<div>openssl/libssl3</div> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>3.0.11-1~deb12u2</td><td>3.0.13-1~deb12u1</td></tr></table>	Impacted Version	Fixed Version	3.0.11-1~deb12u2	3.0.13-1~deb12u1	<div>Jun 10, 2024</div> <div>01:16:16</div>	<div>Containers</div> <div>kube-proxy-kvh2j</div>

CVE-2023-6129	<p>Issue summary: The POLY1305 MAC (message authentication code) implementation contains a bug that might corrupt the internal state of applications running on PowerPC CPU based platforms if the CPU provides vector instructions. Impact summary: If an attacker can influence whether the POLY1305 MAC algorithm is used, the application state might be corrupted with various application dependent consequences. The POLY1305 MAC (message authentication code) implementation in OpenSSL for PowerPC CPUs restores the contents of vector registers in a different order than they are saved. Thus the contents of some of these vector registers are corrupted when returning to the caller. The vulnerable code is used only on newer PowerPC processors supporting the PowerISA 2.07 instructions. The consequences of this kind of internal application state corruption can be various - from no consequences, if the calling application does not depend on the contents of non-volatile XMM registers at all, to the worst consequences, where the attacker could get complete control of the application process. However unless the compiler uses the vector registers for storing pointers, the most likely consequence, if any, would be an incorrect result of some application dependent calculations or a crash leading to a denial of service. The POLY1305 MAC algorithm is most frequently used as part of the CHACHA20-POLY1305 AEAD (authenticated encryption with associated data) algorithm. The most common usage of this AEAD cipher is with TLS protocol versions 1.2 and 1.3. If this cipher is enabled on the server a malicious client can influence whether this AEAD cipher is used. This implies that TLS server</p>	<div>V2: 4</div> <div>V3: 6.5</div>	<div>openssl/libssl3</div> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>3.0.11-1~deb12u2</td><td>3.0.13-1~deb12u1</td></tr></table>	Impacted Version	Fixed Version	3.0.11-1~deb12u2	3.0.13-1~deb12u1	<div>May 3, 2024</div> <div>09:15:21</div>	<div>Containers</div> <div>kube-proxy-kvh2j</div>

CVE-2023-5678	<p>Issue summary: Generating excessively long X9.42 DH keys or checking excessively long X9.42 DH keys or parameters may be very slow. Impact summary: Applications that use the functions DH_generate_key() to generate an X9.42 DH key may experience long delays. Likewise, applications that use DH_check_pub_key(), DH_check_pub_key_ex() or EVP_PKEY_public_check() to check an X9.42 DH key or X9.42 DH parameters may experience long delays. Where the key or parameters that are being checked have been obtained from an untrusted source this may lead to a Denial of Service. While DH_check() performs all the necessary checks (as of CVE-2023-3817), DH_check_pub_key() doesn't make any of these checks, and is therefore vulnerable for excessively large P and Q parameters. Likewise, while DH_generate_key() performs a check for an excessively large P, it doesn't check for an excessively large Q. An application that calls DH_generate_key() or DH_check_pub_key() and supplies a key or parameters obtained from an untrusted source could be vulnerable to a Denial of Service attack. DH_generate_key() and DH_check_pub_key() are also called by a number of other OpenSSL functions. An application calling any of those other functions may similarly be affected. The other functions affected by this are DH_check_pub_key_ex(), EVP_PKEY_public_check(), and EVP_PKEY_generate(). Also vulnerable are the OpenSSL pkey command line application when using the "-pubcheck" option, as well as the OpenSSL genpkey command line application. The OpenSSL SSL/TLS implementation is not affected by this issue. The OpenSSL 3.0 and 3.1 FIPS providers are not</p>	<div>V2: 4</div> <div>V3: 5.3</div>	<div>openssl/libssl3</div> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>3.0.11-1~deb12u2</td><td>3.0.13-1~deb12u1</td></tr></table>	Impacted Version	Fixed Version	3.0.11-1~deb12u2	3.0.13-1~deb12u1	<div>May 1, 2024</div> <div>02:15:12</div>	<div>Containers</div> <div>kube-proxy-kvh2j</div>

CVE-2023-49295	<p>quic-go's path validation mechanism can be exploited to cause denial of service</p> <p>An attacker can cause its peer to run out of memory sending a large number of PATH_CHALLENGE frames. The receiver is supposed to respond to each PATH_CHALLENGE frame with a PATH_RESPONSE frame. The attacker can prevent the receiver from sending out (the vast majority of) these PATH_RESPONSE frames by collapsing the peers congestion window (by selectively acknowledging received packets) and by manipulating the peer's RTT estimate.</p> <p>I published a more detailed description of the attack and its mitigation in this blog post: https://seemann.io/posts/2023-12-18-exploiting-quics-path-validation/</p> <p>There's no way to mitigate this attack, please update quic-go to a version that contains the fix.</p>	V2: 4 V3: 6.4	<div>go:github.com/quic-go/quic-go</div> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>0.37.4</td><td>0.40.1;0.39.4;0.38.2;0.37.7</td></tr></table>	Impacted Version	Fixed Version	0.37.4	0.40.1;0.39.4;0.38.2;0.37.7	Jan 10, 2024 10:08:40	Containers coredns-7db6d8ff4d-8tkdq

CVE-2023-48795	<p>Prefix Truncation Attack against ChaCha20-Poly1305 and Encrypt-then-MAC aka Terrapin</p> <p>### Summary</p> <p>Terrapin is a prefix truncation attack targeting the SSH protocol. More precisely, Terrapin breaks the integrity of SSH's secure channel. By carefully adjusting the sequence numbers during the handshake, an attacker can remove an arbitrary amount of messages sent by the client or server at the beginning of the secure channel without the client or server noticing it.</p> <p>### Mitigations</p> <p>To mitigate this protocol vulnerability, OpenSSH suggested a so-called "strict kex" which alters the SSH handshake to ensure a Man-in-the-Middle attacker cannot introduce unauthenticated messages as well as convey sequence number manipulation across handshakes.</p> <p>**Warning: To take effect, both the client and server must support this countermeasure.**</p> <p>As a stop-gap measure, peers may also (temporarily) disable the affected algorithms and use unaffected alternatives like AES-GCM instead until patches are available.</p> <p>### Details</p> <p>The SSH specifications of ChaCha20-Poly1305 (chacha20-poly1305@openssh.com) and Encrypt-then-MAC (*-etm@openssh.com MACs) are vulnerable against an arbitrary prefix truncation attack (a.k.a. Terrapin attack). This allows for an extension negotiation downgrade by stripping the SSH_MSG_EXT_INFO sent after the first message after SSH_MSG_NEWKEYS, downgrading security, and disabling attack countermeasures in some</p>	<p>V2: 4</p> <p>V3: 5.9</p>	<div>go:golang.org/x/crypto</div> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>0.12.0</td><td>0.17.0</td></tr><tr><td>0.0.0-20201002170205-7f63de1d35b0</td><td>0.17.0</td></tr></table>	Impacted Version	Fixed Version	0.12.0	0.17.0	0.0.0-20201002170205-7f63de1d35b0	0.17.0	<p>Dec 18, 2023 02:22:09</p>	<p>Containers</p> <p>coredns-7db6d8ff4d-8tkdq</p> <p>storage-provisioner</p>

	<p>versions of OpenSSH. When targeting Encrypt-then-MAC, this attack requires the use of a CBC cipher to be practically exploitable due to the internal workings of the cipher mode. Additionally, this novel attack technique can be used to exploit previously unexploitable implementation flaws in a Man-in-the-Middle scenario.</p> <p>The attack works by an attacker injecting an arbitrary number of SSH_MSG_IGNORE messages during the initial key exchange and consequently removing the same number of messages just after the initial key exchange has concluded. This is possible due to missing authentication of the excess SSH_MSG_IGNORE messages and the fact that the implicit sequence numbers used within the SSH protocol are only checked after the initial key exchange.</p> <p>In the case of ChaCha20-Poly1305, the attack is guaranteed to work on every connection as this cipher does not maintain an internal state other than the message's sequence number. In the case of Encrypt-Then-MAC, practical exploitation requires the use of a CBC cipher; while theoretical integrity is broken for all ciphers when using this mode, message processing will fail at the application layer for CTR and stream ciphers.</p> <p>For more details see [https://terrapin-attack.com] (https://terrapin-attack.com).</p> <p>### Impact</p> <p>This attack targets the specification of ChaCha20-Poly1305 (chacha20-poly1305@openssh.com) and Encrypt-then-MAC (*-etm@openssh.com), which are widely adopted by well-known SSH implementations and can be considered de-facto standard. These</p>

	algorithms can be practically exploited; however, in the case of Encrypt-Then-MAC, we additionally require the use of a CBC cipher. As a consequence, this attack works against all well-behaving SSH implementations supporting either of those algorithms and can be used to downgrade (but not fully strip) connection security in case SSH extension negotiation (RFC8308) is supported. The attack may also enable attackers to exploit certain implementation flaws in a man-in-the-middle (MitM) scenario.

CVE-2023-45288	net/http, x/net/http2: close connections when receiving too many headers	V2: 4 V3: 5.3			Apr 4, 2024 05:30:32	Containers coredns-7db6d8ff4d-8tkdq etcd-minikube storage-provisioner								
	An attacker may cause an HTTP/2 endpoint to read arbitrary amounts of header data by sending an excessive number of CONTINUATION frames. Maintaining HPACK state requires parsing and processing all HEADERS and CONTINUATION frames on a connection. When a request's headers exceed MaxHeaderBytes, no memory is allocated to store the excess headers, but they are still parsed. This permits an attacker to cause an HTTP/2 endpoint to read arbitrary amounts of header data, all associated with a request which is going to be rejected. These headers can include Huffman-encoded data which is significantly more expensive for the receiver to decode than for an attacker to send. The fix sets a limit on the amount of excess header frames we will process before closing a connection.		go:golang.org/x/net

CVE-2023-44487	<p>HTTP/2 Stream Cancellation Attack</p> <p>## HTTP/2 Rapid reset attack</p> <p>The HTTP/2 protocol allows clients to indicate to the server that a previous stream should be canceled by sending a RST_STREAM frame. The protocol does not require the client and server to coordinate the cancellation in any way, the client may do it unilaterally. The client may also assume that the cancellation will take effect immediately when the server receives the RST_STREAM frame, before any other data from that TCP connection is processed. Abuse of this feature is called a Rapid Reset attack because it relies on the ability for an endpoint to send a RST_STREAM frame immediately after sending a request frame, which makes the other endpoint start working and then rapidly resets the request. The request is canceled, but leaves the HTTP/2 connection open.</p> <p>The HTTP/2 Rapid Reset attack built on this capability is simple: The client opens a large number of streams at once as in the standard HTTP/2 attack, but rather than waiting for a response to each request stream from the server or proxy, the client cancels each request immediately.</p> <p>The ability to reset streams immediately allows each connection to have an indefinite number of requests in flight. By explicitly canceling the requests, the attacker never exceeds the limit on the number of concurrent open streams. The number of in-flight requests is no longer dependent on the round-trip time (RTT), but only on the available network bandwidth.</p> <p>In a typical HTTP/2 server implementation, the server will still have to do significant amounts of work for</p>	<p>V2: 4</p> <p>V3: 5.3</p>	<p>go:golang.org/x/net</p> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>0.0.0-20201224014010-6772e930b67b</td><td>0.17.0</td></tr><tr><td>0.14.0</td><td>0.17.0</td></tr></table> <p>go:google.golang.org/grpc</p> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>1.57.0</td><td>1.58.3;1.57.1;1.56.3</td></tr></table>	Impacted Version	Fixed Version	0.0.0-20201224014010-6772e930b67b	0.17.0	0.14.0	0.17.0	Impacted Version	Fixed Version	1.57.0	1.58.3;1.57.1;1.56.3	<p>Oct 10, 2023 05:28:24</p>	<p>Containers</p> <p>coredns-7db6d8ff4d-8tkdq</p> <p>storage-provisioner</p>

	<p>canceled requests, such as allocating new stream data structures, parsing the query and doing header decompression, and mapping the URL to a resource. For reverse proxy implementations, the request may be proxied to the backend server before the RST_STREAM frame is processed. The client on the other hand paid almost no costs for sending the requests. This creates an exploitable cost asymmetry between the server and the client.</p> <p>Multiple software artifacts implementing HTTP/2 are affected. This advisory was originally ingested from the `swift-nio-http2` repo advisory and their original content follows.</p> <p>## swift-nio-http2 specific advisory</p> <p>swift-nio-http2 is vulnerable to a denial-of-service vulnerability in which a malicious client can create and then reset a large number of HTTP/2 streams in a short period of time. This causes swift-nio-http2 to commit to a large amount of expensive work which it then throws away, including creating entirely new `Channel`s to serve the traffic. This can easily overwhelm an `EventLoop` and prevent it from making forward progress.</p> <p>swift-nio-http2 1.28 contains a remediation for this issue that applies reset counter using a sliding window. This constrains the number of stream resets that may occur in a given window of time. Clients violating this limit will have their connections torn down. This allows clients to continue to cancel streams for legitimate reasons, while constraining malicious actors.</p>

CVE-2023-39325	<p>HTTP/2 rapid reset can cause excessive work in net/http</p> <p>A malicious HTTP/2 client which rapidly creates requests and immediately resets them can cause excessive server resource consumption. While the total number of requests is bounded by the http2.Server.MaxConcurrentStreams setting, resetting an in-progress request allows the attacker to create a new request while the existing one is still executing.</p> <p>With the fix applied, HTTP/2 servers now bound the number of simultaneously executing handler goroutines to the stream concurrency limit (MaxConcurrentStreams). New requests arriving when at the limit (which can only happen after the client has reset an existing, in-flight request) will be queued until a handler exits. If the request queue grows too large, the server will terminate the connection.</p> <p>This issue is also fixed in golang.org/x/net/http2 for users manually configuring HTTP/2.</p> <p>The default stream concurrency limit is 250 streams (requests) per HTTP/2 connection. This value may be adjusted using the golang.org/x/net/http2 package; see the Server.MaxConcurrentStreams setting and the ConfigureServer function.</p>	<p>V2: 7</p> <p>V3: 7.5</p>	<p>go:golang.org/x/net</p> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>0.0.0-20201224014010-6772e930b67b</td><td>0.17.0</td></tr><tr><td>0.14.0</td><td>0.17.0</td></tr></table>	Impacted Version	Fixed Version	0.0.0-20201224014010-6772e930b67b	0.17.0	0.14.0	0.17.0	<p>Oct 11, 2023</p> <p>04:35:43</p>	<p>Containers</p> <p>coredns-7db6d8ff4d-8tkdq</p> <p>storage-provisioner</p>

CVE-2023-29383	<p>In Shadow 4.13, it is possible to inject control characters into fields provided to the SUID program chfn (change finger). Although it is not possible to exploit this directly (e.g., adding a new user fails because \n is in the block list), it is possible to misrepresent the /etc/passwd file when viewed. Use of \r manipulations and Unicode characters to work around blocking of the : character make it possible to give the impression that a new user has been added. In other words, an adversary may be able to convince a system administrator to take the system offline (an indirect, social-engineered denial of service) by demonstrating that "cat /etc/passwd" shows a rogue user account.</p>	<div>V2: 1</div> <div>V3: 3.3</div>	<div>shadow/login</div> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>1:4.8.1-2ubuntu2.2</td><td>N/A</td></tr><tr><td>1:4.8.1-1ubuntu5.20.04.5</td><td>N/A</td></tr></table> <div>shadow/passwd</div> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>1:4.8.1-2ubuntu2.2</td><td>N/A</td></tr><tr><td>1:4.8.1-1ubuntu5.20.04.5</td><td>N/A</td></tr></table>	Impacted Version	Fixed Version	1:4.8.1-2ubuntu2.2	N/A	1:4.8.1-1ubuntu5.20.04.5	N/A	Impacted Version	Fixed Version	1:4.8.1-2ubuntu2.2	N/A	1:4.8.1-1ubuntu5.20.04.5	N/A	<div>Apr 24, 2023</div> <div>02:05:30</div>	<div>Nodes</div> <div>minikube</div> <div>Containers</div> <div>dh157-ubuntu</div> <div>ubuntu</div>

CVE-2023-26604	systemd before 247 does not adequately block local privilege escalation for some Sudo configurations, e.g., plausible sudoers files in which the "systemctl status" command may be executed. Specifically, systemd does not set LESSSECURE to 1, and thus other programs may be launched from the less program. This presents a substantial security risk when running systemctl from Sudo, because less executes as root when the terminal size is too small to show the complete systemctl output. CVE-2022-40735	<p>The Diffie-Hellman Key Agreement Protocol allows use of long exponents that arguably make certain calculations unnecessarily expensive, because the 1996 van Oorschot and Wiener paper found that "(appropriately) short exponents" can be used when there are adequate subgroup constraints, and these short exponents can lead to less expensive calculations than for long exponents. This issue is different from CVE-2002-20001 because it is based on an observation about exponent size, rather than an observation about numbers that are not public keys. The specific situations in which calculation expense would constitute a server-side vulnerability depend on the protocol (e.g., TLS, SSH, or IKE) and the DHE implementation details. In general, there might be an availability concern because of server-side resource consumption from DHE modular-exponentiation calculations. Finally, it is possible for an attacker to exploit this vulnerability and CVE-2002-20001 together.</p>	<div>V2: 7</div> <div>V3: 7.5</div>	<div>openssl</div> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>3.0.2-0ubuntu1.15</td><td>3.0.2-0ubuntu1.16</td></tr></table> <div>openssl/libssl3</div> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>3.0.2-0ubuntu1.15</td><td>3.0.2-0ubuntu1.16</td></tr></table>	Impacted Version	Fixed Version	3.0.2-0ubuntu1.15	3.0.2-0ubuntu1.16	Impacted Version	Fixed Version	3.0.2-0ubuntu1.15	3.0.2-0ubuntu1.16	<div>Apr 23, 2024</div> <div>03:15:42</div>	<div>Nodes</div> <div>minikube</div>

CVE-2022-32149	<p>golang.org/x/text/language Denial of service via crafted Accept-Language header</p> <p>The BCP 47 tag parser has quadratic time complexity due to inherent aspects of its design. Since the parser is, by design, exposed to untrusted user input, this can be leveraged to force a program to consume significant time parsing Accept-Language headers.</p> <p>The parser cannot be easily rewritten to fix this behavior for various reasons. Instead the solution implemented in this CL is to limit the total complexity of tags passed into ParseAcceptLanguage by limiting the number of dashes in the string to 1000. This should be more than enough for the majority of real world use cases, where the number of tags being sent is likely to be in the single digits.</p> <p>### Specific Go Packages Affected</p> <p>golang.org/x/text/language</p>	<p>V2: 7</p> <p>V3: 7.5</p>	<p>go:golang.org/x/text</p> <table><tr><th>Impacted Version</th><th>Fixed Version</th></tr><tr><td>0.3.5</td><td>0.3.8</td></tr></table>	Impacted Version	Fixed Version	0.3.5	0.3.8	<p>Oct 14, 2022 03:00:40</p>	<p>Containers storage-provisioner</p>
